

The implementation of Bifrostconnect Front-end  
scope, re-design and development with the  
relevant back-end support develop.

Fei Gu

December 31, 2023

# **1 Introduction**

## **1.1 The project type**

This project is the final project of the EASV computer science program. The purpose of the final project is to demonstrate the knowledge and skills by the student during the two and a half years of study, and be able to fully demonstrate them in a project.

In this project, the student will work with a company to solve a problem of the company. The student will use the knowledge and skills learned from the education to solve the problem.

Which means this project will relevant to the company's business domain, and using the software engineering methods and software development methods to recognize the problem, analyze the problem, and solve the problem.

## **1.2 About the company**

BifrostConnect is a startup company which established in 2018 that has 10 to 12 employees and located in Copenhagen, Denmark.

During the five years of operation, the company has developed a remote access solution for access the users remote system. The solution

The company's main business is to solve the problem of remote access to the customer's system when the customer's system does not have and is not allowed to have the Internet under strict system security conditions.

The company's product is a hardware device and a network application. And related services and one-stop solutions.

## **1.3 About the project**

This project is to re-design and re-develop the front-end software based on the company's original software, and provide corresponding support on the back-end.

## 2 Problem Statement

### 2.1 Statement

During this project the Remote Access Interface and Tunnel Interface should be integrated into the Device Manager Application. To achieve the one single page application with full functionality of the Remote Access and Tunnel Connection capabilities.

### 2.2 Situation

The current BifrostConnect front-end application consist of the Device Manager (DM) and Remote Access Interface (RAI) two different user interface. Which means the user need to manage their devices and users in the one application, and operate their devices to use the bifrost product in other web application as well. However, the RAI consists of two different user interfaces referred to as the Classic RAI and Tunnel RAI. Those two user interfaces will leading the user to different web application when user wish to create a different type of access solution.

The reason for this situation occurred is because the bifrost product is developed focus on the device and the application part was not considered as important as the device part. Therefore, the application part was developed by different developers with different design logic. And the application functionality was not been properly through out the development process. Which cause the design logic of this product is not scalable, leading to decreasing user experience, and exponential growth of code complexity which makes it increasingly challenging to maintain and improve. Also the product design style lacks scalability due to lack of modularity and code consistency, and the operation logic is not clear.

### 2.3 Potential Solution

To address those issue, there is a need to redesign and remake the front-end with a focus on implementing a modular unified front-end management system that encompasses all the necessary functionality.

The goal is to provide users with seamless control, monitoring, and access to their devices from anywhere, enhancing their overall user experience and productivity while keeping code complexity as low as possible.

For the implementation to be successful, we also need to have a back-end service, including an API and Database. The back-end server will contain the necessary service for the front-end to reach the purpose. Such as the RESTful API service, authentication service, MQTT service, Tunnel service and Database.

This project will follow the software design process. Therefore, it will also include the Software Development method and DevOps on all process as well.

This project is covered by NDA due to security and confidentiality reasons. Thus, the project will initially not be publicly deployed, however, I will described

the deployment in my report as well.

## 3 Requirement Analysis

### 3.1 Stakeholders

During this project. There are three stakeholders who are involved in this project. The user, the developer and the project owner.

#### 3.1.1 User

The user is the person who will use the system. In this project, we can easily identify the user is the customer who will use the web application to manage their device and users, and create the RAI and Tunnel.

The user in this project are require the web application should be operate easily, the features in this web application can be recognized easily and the usage should be obvious.

#### 3.1.2 Developer

The developer is the person who will develop, modify, scale and fix the system in any situation.

Therefore, the entire system should be easy to understand with the comments, easy to modify with the clear structure, easy to scale with reusable components and easy to identify the issue to fix any bugs.

#### 3.1.3 Project Owner

The project owner is the person who will manage the project, in this case, the project owner is the company who own the product.

The project owner is require the project should be finished in time, can be cooperate with the hardware which be developed by the company, and the project can be easily to maintain, update, migration, and handover to other developers.

### 3.2 Scope

The scope of this project is to develop a web application which can be used to manage the device and users, and create the RAI and Tunnel.

Because the device manager already exist, the main focus will be on the implementation of the RAI and Tunnel into the device manager. Which means we don't need to develop the device manager, also there are no necessary to develop the new features for the RAI and Tunnel interface.

Because the situation of the entire system was redundant and coupling, we have to re-design the system components and identify the relationship between them. The re-design of the system will be the main focus of this project.

Since the Device Manager is written in React framework, we have to use the same framework to develop the RAI and Tunnel interface.

### **3.3 Goals**

The goal of this project is to develop a RAI and Tunnel interface in the Device Manager. The RAI and Tunnel interface should be able to create, modify, delete and view the access connection. Also can remote control the device and target equipment.

### **3.4 Bussines Domain**

## 4 Software Development Methods

### 4.1 Agile Software Development

The Agile software development is a set of software development methods to aim to provide a sustainable, iterative and incremental software development process.

The Agile promotes adaptive planning, evolutionary development, early delivery, and continuous improvement, and it encourages rapid and flexible response to change. []

### 4.2 Unified Process

The unified software development process or unified process is an iterative and incremental software development process framework. This framework is based on the Agile incremental and iterative software development process.

In this project, the unified process is used as the definition of the software development process. The UP method such as the use case driven development, the iterative and incremental development are used in each phase of this project.

### 4.3 Feature Driven Development

"Feature Driven Development (FDD) is an iterative and incremental software development process." [1]

The FDD is a model-driven short-iteration process that consists of five basic activities:

1. Develop an overall model
2. Build a feature list
3. Plan by feature
4. Design by feature
5. Build by feature

#### 4.3.1 Develop an overall model

The first step of the FDD is to develop an overall model. The overall model is a domain model that proposed to let the application can have a basic structure and can be run for no feature. After the overall model is developed, the feature list can be created for adding the features to the application.

In this project, the overall model is more like a prototype or demo of the application.

**Front-end overall model** At the front-end side, the overall model is a simple web page that can be used to show the basic structure of the application. Following the core concept of the React, the front end overall model will be only represents the view of the application.

**Back-end overall model** At the back-end side, the overall model is data server which have the basic structure and a simple data model. The prepose of the backend overall model is not to provide any of the service or interface to eather the front-end or the database. It only use for the architecrure design to make sure the server side scalable and modular.

**Database overall model** The database overall model will indentify the bussiness domain of the application which is relavent to the device, user, and the data of the application.

#### **4.3.2 Feature list**

The feature list is a list of the features that the application will have. It will following the use-case that be indentify in the user story. And connect the all front-end, back-end and database together. Therefore, the each feature will produce the sequence start from the front-end to the back-end and then to the database, and return the result to the front-end to display to the user.

## 5 Software Design

### 5.1 Technology selection

According to the requirements of this project. We need to build a full-stack B/S system with the database and other service.

#### 5.1.1 Front-end

**JAVASCRIPT** is the most popular language for the front-end development.

**React** is a JavaScript library for building user interfaces. It is maintained by Facebook and a community of individual developers and companies. React can be used as a base in the development of single-page or mobile applications. However, React is only concerned with state management and rendering that state to the DOM, so creating React applications usually requires the use of additional libraries for routing, as well as certain client-side functionality. React Router is an example of such a library.

**React-Router** is a routing library for React. It abstracts away the details of server and client and allows developers to focus on building apps. It offers a simple, declarative API to let you build URL (Uniform Resource Locator) routing with ease. It supports server-side rendering and comes with routers for browsers and Node.js.

**Redux** is a predictable state container for JavaScript apps. It helps you write applications that behave consistently, run in different environments (client, server, and native), and are easy to test. On top of that, it provides a great developer experience, such as live code editing combined with a time traveling debugger.

**RTK** is a powerful, opinionated Redux toolset for writing better reducers, organizing and accessing state in components, and managing side effects. It was originally created to help address three common concerns about Redux:

**RTKQ** is a powerful data fetching and caching tool. It is designed to simplify common cases for loading data in a web application, eliminating the need to hand-write data fetching & caching logic yourself.

**TailwindCSS** is a utility-first CSS framework for rapidly building custom user interfaces. It is a highly customizable, low-level CSS framework that gives you all of the building blocks you need to build bespoke designs without any annoying opinionated styles you have to fight to override.

**Semantic UI** is a development framework that helps create beautiful, responsive layouts using human-friendly HTML. Semantic UI treats words and classes as exchangeable concepts. Classes use syntax from natural languages like noun/modifier relationships, word order, and plurality to link concepts intuitively.

**Jest** is a JavaScript testing framework maintained by Facebook, Inc. designed and built by Christoph Nakazawa with a focus on simplicity and support for large web applications. It works with projects using Babel, TypeScript, Node.js, React, Angular, Vue.js and Svelte. Jest does not require a browser to run tests, and it runs tests in parallel - this makes Jest fast. Jest is well-documented, requires little configuration and can be extended to match your requirements.

### 5.1.2 Back-end

**C#** is a general-purpose, multi-paradigm programming language.

**ASP.NET Core** is a cross-platform, high-performance, open-source framework for building modern, cloud-based, Internet-connected applications.

**Entity Framework Core** is a modern object-database mapper for .NET. It supports LINQ queries, change tracking, updates, and schema migrations. EF Core works with SQL Server, Azure SQL Database, SQLite, Azure Cosmos DB, MySQL, PostgreSQL, and other databases through a provider plugin API.

### 5.1.3 Database

**SQLite** is a C-language library that implements a small, fast, self-contained, high-reliability, full-featured, SQL database engine.

### 5.1.4 Data communication

**HTTP** is an application-layer protocol for transmitting hypermedia documents, such as HTML. It was designed for communication between web browsers and web servers, but it can also be used for other purposes. HTTP follows a classical client-server model, with a client opening a connection to make a request, then waiting until it receives a response. HTTP is a stateless protocol, meaning that the server does not keep any data (state) between two requests. Though often based on a TCP/IP layer, it can be used on any reliable transport layer; that is, a protocol that doesn't lose messages silently, such as UDP.

**Flatbuffers** is an efficient cross platform serialization library for C++, C#, C, Go, Java, JavaScript, Lobster, Lua, TypeScript, PHP, Python, and Rust. It was originally created at Google for game development and other performance-critical applications.

**MQTT** is a machine-to-machine (M2M)/"Internet of Things" connectivity protocol. It was designed as an extremely lightweight publish/subscribe messaging transport. It is useful for connections with remote locations where a small code footprint is required and/or network bandwidth is at a premium.

**webrtc** is a free, open-source project that provides web browsers and mobile applications with real-time communication (RTC) via simple application programming interfaces (APIs). It allows audio and video communication to work inside web pages by allowing direct peer-to-peer communication, eliminating the need to install plugins or download native apps.

**WebRTC Datachannel** is a component of WebRTC that enables peer-to-peer exchange of arbitrary data between two devices. It was added to the WebRTC standard by the World Wide Web Consortium (W3C) in January 2015.

#### 5.1.5 DevOps

**Git** is a distributed version-control system for tracking changes in source code during software development. It is designed for coordinating work among programmers, but it can be used to track changes in any set of files. Its goals include speed, data integrity, and support for distributed, non-linear workflows.

**GitHub** is a provider of Internet hosting for software development and version control using Git. It offers the distributed version control and source code management (SCM) functionality of Git, plus its own features. It provides access control and several collaboration features such as bug tracking, feature requests, task management, and wikis for every project.

**GitHub Actions** is an API for cause and effect on GitHub: orchestrate any workflow, based on any event, while GitHub manages the execution, provides rich feedback, and secures every step along the way. With GitHub Actions, workflows and steps are just code in a repository, so you can create, share, reuse, and fork your software development practices.

**Docker** is a set of platform as a service (PaaS) products that use OS-level virtualization to deliver software in packages called containers. Containers are isolated from one another and bundle their own software, libraries and configuration files; they can communicate with each other through well-defined channels. All containers are run by a single operating system kernel and are thus more lightweight than virtual machines. Containers are created from images that specify their precise contents. Images are often created by combining and modifying standard images downloaded from public repositories.

## **5.2 Architecture design**

### **5.2.1 overall architecture**

In this project, the overall architecture design is based on C/S architecture, The client is a web browser. All the user interaction is done through the web browser. The uses operation include require data, display infomation, modify data, configure the device, create and oprating a classic remote access and tunnel will be happen in the web browser which is the frontEnd of the system.

### **5.2.2 Front-end**

**Front-end architecture**

**Front-end data flow**

### **5.2.3 Back-end**

**Back-end architecture**

**Back-end data flow**

### **5.2.4 Data communication and storage**

## **5.3 Domain model**

## **5.4 Database design**

## **5.5 Back-end design**

## **5.6 Front-end design**

## **5.7 FlatBuffers design**

## **5.8 DevOps CI/CD process design**

### **5.8.1 Version Control**

### **5.8.2 Branching Strategy**

### **5.8.3 Continuous Integration**

### **5.8.4 Continuous Delivery**

### **5.8.5 Continuous Deployment**

## **6 Software Development**

**6.1 Front-end**

**6.2 Back-end**

**6.3 Database**

**6.4 WebRTC**

**6.5 MQTT**

**6.6 RESTful API**

**6.7 Authentication**

## **7 Conclusion**

### **7.1 Result**

### **7.2 Discussion**

### **7.3 Future Work**
